The Long-Run Effects of Doxxing: Evidence from the Second Ku Klux Klan

I provide the first quantitative analysis on the long-run effects of doxxing—the act of releasing someone’s personally identifiable information as a form of retaliation—using linked census data on KKK members from 1900-1940. Using difference-in-differences and event study techniques, I show that Klansmen who had their names, addresses, and occupations exposed by the anti-Klan publication *Tolerance* fared no differently through 1940 in terms of migration, job switching, and occupational prestige relative to their unexposed counterparts. However, self-employed Klansmen and those living in enumeration districts with above-median minority representation were significantly more likely to change industries of employment and move to a new county.

Crony Capitalism and Insider Trading: Insights from the Teapot Dome Scandal (with C. Fohlin) | *Under Review*

Using novel data from the notorious 1922 Teapot Dome scandal, we assess costs of informed trading by corrupt officials and company insiders involved in illegal federal oil lease contracts. We estimate insider gains of nearly \$300 million (2025 terms). Market makers widened bid-ask spreads for oil stocks, raising costs for all investors. Despite legal insider trading, insiders only partially bid up share prices before public revelation, temporarily evading detection and delaying full information incorporation until salient news coverage broke. Our analysis underscores how cronyism and insider trading distort resource allocation and disadvantage uninformed investors, with lessons for modern regulation.
